Airronbot — Discord Community Software

Project brief

Airronbot brings birthday reminders, welcome messages, moderator announcements and slash commands into a Discord community. Addressed messages are filtered and sent to a separate external relay, whose authenticated callback delivers text and optional queued speech. The project also includes duplicate protection, voice-state handling and a health dashboard. This is an AI-assisted personal project, and the portfolio distinguishes documented capabilities, generated or adapted code and behavior that still needs a fresh end-to-end demonstration.

Ownership

Personal AI-assisted software project

Evidence focus

Follow the path from a Discord event through filtering, relay transport, callback validation and delivery. The inspected code and operations README make the preview/production boundary and queued-versus-finished voice states explicit.

Scope

The bot itself does not generate AI answers or search the web; the external relay is a separate dependency. Published metadata is not proof of a new Discord/voice test, and the exported source is a selected snapshot without secrets or birthday records.

Skills

Event-driven integration, API validation, permissions, deduplication, observability
